Abstract-The objects of this study are the wildly-growing grass of the species Ziziphora clinopodioides Lam. collected in the flowering phase in April-July 2013 from the mountains of the villages Voghjaberd, Hankavan, Arzakan and the grass Ziziphora cultured in the hydroponic conditions.

For the first time, the numerical characteristics of the merchandising quality control for raw material of the Ziziphora clinopodioides Lam. were defined from wild-growing plants (Voghjaberd, Hankavan, Arzakan) and grown up in a hydroponics.

The highest value of the essential oil yield differs raw material collected in the condition of hydroponics 1.25 ± 0.01%, for the relative density differs raw material collected in the vicinity of the village Hankavan-0.977 ± 0.001, for the refractive index differs raw materials collected in the vicinity of the village Arzakan 1.490 ± 0.003.

The highest values for the total extractive composition /50 ° spirits / and humidity differs raw material collected in Arzakan 29.0 ± 0.01% , 8.8 ± 0.15%, respectively, for the ash - hydroponics 9.1 ± 0.02%.

By the method of gas chromatography-mass spectrometry, the above studied samples revealed for the first time more than 80 components, among which there were the following main components:(±) pulegone (16,62-25,71%), verbenone (7,78-14,33%), eucalyptol (8,94-12,98%), DL (+) menthol (1,48-10,02%), isomenthone (3,42-6,05%), D-menthone (5,13-6,85%), D (±) limonene (1,3-6,47%), thymol (0,73-0,41%).

Keywords-Ziziphora clinopodioides Lam., essential oils, density, refractive index, gas chromatography-mass spectrometry (key words)

I. Introduction

In recent years, the arsenal of the medicinal plants and the herbal medicines has been significantly increased on the global pharmaceutical market. The essential oils production is concentrated mainly in the southern countries, which are the main sources of raw materials [1,2].

The plant Ziziphora clinopodioides Lam. has the scientific interest among the raw material sources of the essential oils. This plant is used mostly in traditional medicine as sedative and carminative, anti-vomiting and anti-inflammatory and antiseptic in different foods and also in traditional medicines for treatment of digestive and viral diseases, on the interaction between these compounds and yoghurt starter culture activity [3,4,5].

The analysis of the international scientific literature shows that Ziziphora clinopodioides Lam. is one of the most promising plants for the essential oils production as well as the raw source of flavonoids which determine the biological activity of the wild-growing species [6,7,8].

The chemical composition of the essential oil obtained from the aerial parts of Ziziphora clinopodioides Lam. was analyzed by the gas chromatography-mass spectrometry (GC-MS) method. Twenty six components representing 97.6% - 97.62 % of the total oil were identified. The major constituents were pulegone (34.4%-36.45%), piperitenone (15.1%-19.12%), 1-8- cineole (6.5%), neo-menthol (5.7%-7.78%), menth-2-en-1- ol (5.3%-5.31%), menthol (5.2%), carvacrol (5.1%) and menthone (4.5%-4.46%).

The study of the domestic plant raw material shows, that the flora of Armenia is the most relevant of identifying perspective essential oil plants, and creating the effective medicines. [17,18,19].
From this point of view, the object of studying the species of Ziziphora clinopodioides Lam served wild-growing in the flora of Armenia [20]. Ziziphora L. (Labiatae family) includes about 30 species that are wide-spread in the southern part of Europe, in the Mediterranean region and South-East Asia [21]. The species Ziziphora is one of the most common plants in the flora of Armenia. The raw material resources study indicated that the populations of the wild-growing species Ziziphora met in Armenia as a form of the small scattered semi shrubs in small populations which alternate from the rocky slopes of mountain belts to subalpine elevations.

In the traditional Armenian medicine, Ziziphora clinopodioides var. Serpyllacea is widely used, as the phytocides, cardiotonic and hypotensive means to ease nausea during pregnancy, as well as a fragrance ingredient in the soaps manufacturing and in cosmetic purposes [22]. Thus, the study of the species Ziziphora growing in the flora of Armenia, as a plant of a valuable raw material oils production as well as a source of the flavonoids, acquires a scientific and practical value.

Material and methods.

The objects of this study are the wildly-growing grass of the species Ziziphora clinopodioides Lam. collected in the flowering phase in April-July 2013 from the mountains of the villages Voghjaberd, Hankavan, Arzakan (mountain chain Teksari), adjacent to the eastern and south-western slopes of the ridge Geghama and the grass Ziziphora cultured in the hydroponic conditions (Fig. 1).

Fig.1. The grass Ziziphora clinopodioides Lam. for the first time cultured in the hydroponic conditions.

For the purpose of cultivation, the bushes of Ziziphora were collected near the villages of Voghjberd and Hankavan in the Kotayk region in the middle of April (12.04.13) and were planted on an 5 m² area of the artificial cultivation in the vegetative hydroponics conditions, as well as in the soil per 40 plants. The nutrient black dross in diameter 3-15 mm as a filler was used, which was pre-disinfected by the 0.05% solution of the KMnO₄. As the standard sample, the normal soil culture was used, in which the applicable regulations of agricultural standards were fulfilled [20, 23].

The essential oils were obtained by the method of hydrodistillation (World Health Organization 2011) [24]. According to the merchandising analysis, the quantitative characteristics of raw material quality and the physicochemical parameters of essential oils were determined for all the samples. The macroscopic and microscopic characteristics analysis has been carried out according to the quality control methods for herbal materials [24]. The measurements of the relative density (ρ/ρ₀) at 20°C, were performed by a micropipette firm "Pipette" / Germany / and the analytical electron balance firm "Scientech SA80" / Germany /.

A refractive index was measured by refractometer firm RL-2 / Poland / connected to a thermostat at a standard temperature 20°C.

The chemical composition of the components of the essential oil was investigated by the gas chromatography-mass spectrometry method, gas chromatograph with the mass selective detector manufactured by BRUKER, the USA, was used chromatographic column OPTIMA-FFAP-0.25mm, 60m×0.25mm (ID. MACHEREY-NAGEL, Germany), the qualitative analysis based on the comparison of retention times and the total mass spectra with the corresponding reference data components of oils and pure compounds with the mass spectra data of the library catalog NIST, the flow of helium carrier gas - 1.0ml/min, volume of injected sample 2ml, the evaporator temperature - 220°C, a temperature gradient 50 °C (2min), heated to 250 °C (2.5 °C / min) (retention 5min), split-division 5. The component contents were calculated from the gas chromatographic peak areas.

The components identification was carried out by their retention time and the peak increase by adding a witness. The quantification of the components was determined by the method internal normalization [25].

II. Results and discussions.

The results of the microscopic studies have generated that all the kinds of samples Ziziphora clinopodioides Lam., regardless of climatic conditions of germination and processing features, histologically identical: the round essential oil glands, the unicellular hairs, the stomata anomocytic types are specifically for the family Labiatae (Fig. 2.3).

Fig. 2.3. The results of the microscopic studies.

The results showed, that the yield of essential oil obtained from the raw materials grown up in hydroponics was (1.25 ± 0.01%), Vohchabert (0.85 ± 0.02%), Hankavan (0.79 ± 0.02%), Arzakan (0.78 ± 0.03%) (Tab. 1).
The Tab.I demonstrates, that the greatest amount of the essential oil samples of raw materials are collected in hydroponics (1.25 ± 0.01%), which indicates a favorable effect of growing conditions (black slag) on the intensity of the production of essential oil in plant.

For raw materials collected of the wild-growing plants of the Kotayk region (Vohchabert, Hankavan, Arzakan) was noted almost the same percentage of the essential oil yield (0.78 - 0.85%). The inauthenticity of difference was statistically noted (p>0,05).

* p <0,05 as compared to hydroponics.

As it is known, such physicochemical parameters as the density and the refractive index of essential oil assumes the good quality and the timely collection of raw materials [24, 26].

As our studies showed, the largest amount of essential oils accumulation in the sample growing in the hydroponics, the percentage of which exceeded the others were almost 1.6 times. However, the relative density of the sample was inferior to other samples, indicating to a small amount of oxygen-containing terpenes.

A special attention should be paid to the samples collected near the village Hankavan by a higher value of the relative density. The relative density of the oil of this sample is higher than the other almost 1.07-1.17 times, respectively.

The relative density of the samples grown up in hydroponics (0.857 ± 0.002), is inferior to the other samples, indicating to a small amount of oxygen-containing compounds, as well as the timeliness of the collection of raw materials in a hydroponics (Tab. I,II).

More than 80 components were found by the gas chromatography-mass spectrometry method in the composition of the essential oils of the samples № I-IV Ziziphora(Fig.4-7 ,Tab. IV).

Chromatographic studies (GC-MS) revealed that all the samples of essential oils as in the qualitative composition as well as in quantitative contents of the main components were similar. Differences in the quantitative content of some components are caused not only to climatic factors, but also the growing conditions.

The great attention should be given to the fact that the main components in the all 4 samples are the monoterpenes; (+) pulegone (16.62-25.71%), verbenone (7.78-14.33%), eucalyptol (8.94-12.98%), DL (+) menthol (1.48-10.02%), 5. D-isomenthone (3.42-8.05%), 6. 1 - menthone (5.13-6.85%), 7. D - menthone (3.53-7.02%).8. DL-carvone (3.18-6.57%), 9.D (±) limonene (1.88-6.47%), 10.timol (0.73-5.41%), 11.γ - terpineol (1.11-5.11%), 12.L- α -terpineol 4.95% 13. β-pinene (0.83-4.99%), 14. o-cymene (0.68-3.23%), 15. camphor (0.32-2.80%), 16. abinene (1.27-2.44%),17.1R-α-pine (0.95-2.36%), 18. α-sabinene (0.17-2.02%), 19. levomenthol 8.46%, 20. L-4-terpineneol 5.55%.

![Fig.5. Gaz-liquid chromatogram of the sample of Vokchaberd](image)

**III. Conclusions.**

- For the first time, the numerical characteristics of the merchandising quality control for raw material of the Ziziphora clinopodioides Lam. were defined from wild-growing plants (Voghjaberd, Hankavan, Arzakan) and grown up in a hydroponics.

- The highest value of the essential oil yield differs raw material collected in the condition of hydroponics 1.25 ± 0.01%, for the relative density differs raw material collected in the vicinity of the village Hankavan - 0.977 ± 0.001, for the refractive index differs raw materials collected in the vicinity of the village Arzakan 1.490 ± 0.003.

- The highest values for the total extractive composition /50 ° spirits / and humidity differs raw material collected in Arzakan 29.0 ± 0.01%, 8.8 ± 0.15%, respectively, for the ash - hydroponics 9.1 ± 0.02%.

- By the method of gas chromatography-mass spectrometry, the above studied samples revealed for the first time more than 80 components, among which there were the following main components:(±) pulegone (16.62-25.71%), verbenone (7.78-14.33%), eucalyptol (8.94-12.98%), DL (+) menthol (1.48-10.02%), isomenthone (3.42-8.05%), 1-menthone (3.53-7.02%), D-menthone (5.13-6.85%), DL-carvone (3.18-6.57%), D (+) limonene (1.3-6.47%), thymol (0.73-5.41%).

- The study results indicated that in the essential oil collected from the plants grown up in hydroponic conditions prevail the bicyclic monoterpenoids (camphene, pinene, sabinene) and sesquiterpenoid D-germacrene, which were absent in the essential oils obtained from the wild growing plants. The dominant monoterpenoids in all the samples are: (+) pulegone (16.62-25.71%), verbenone (7.78-14.33%), eucalyptol (8.94-12.98%), thymol (0.73-5.41%).
